† Extruded products will have strengths approximately 10 percent higher than these values.

① *These typical properties are average for various forms, sizes and methods of manufacture, and may not exactly describe any one particular product.*

② Based on 500,000,000 cycles of completely reversed stress using the R. R. Moore type of machine and specimen.

③ Average of tension and compression moduli. Compression modulus is about 2% greater than tension modulus.

④ Electrical conductor grade, 99.45% minimum aluminum.

⑤ EC-O wire will have an elongation of approximately 23% in 10 inches.

⑥ EC-H19 wire will have an elongation of approximately 1½% in 10 inches.

⑦ Sizes greater than 1½ inches will have strengths slightly lower than these values.

⑧ Extruded products more than ¾ inch thick will have strengths 15 to 20% higher than these values

⑨ Sheet less than 0.040 inch thick will have strengths slightly lower than these values

⑩ Sheet more than 0.062 inch thick will have strengths slightly higher than these values.

⑪ Applicable to sheet and plate products only.

①The alloys listed are those which have been included in Federal Specifications QQ-A-596d, ALUMINUM ALLOYS PERMANENT AND SEMI-PERMANENT MOLD CASTINGS, QQ-A-601d, ALUMINUM ALLOY SAND CASTINGS, and Military Specification MIL-A-21180C, ALUMINUM ALLOY CASTINGS, HIGH STRENGTH. Other alloys are registered with The Aluminum Association and are available. Information on these should be requested from individual foundries or ingot suppliers.

②Analysis is regularly made only for the elements for which specific limits are shown If, however, the presence of other elements is suspected to be, or in the course of routine analysis is indicated to be, in excess of the specified limits, further analysis is made to determine that those other elements are not in excess of the amount Composition in percent maximum unless shown as a range, is the remainder.

stomer should keep in mind that (1) some foundaries may offer
ial tempers for the above alloys, and (2) foundaries are constantly improving casting technique and, as a result, some may guarantee minimum properties in excess of the above.

NOTES

① Troy ounces per avoirdupois ton.

② These are high conductivity coppers which have in the annealed condition a minimum conductivity of 100% IACS.

③ The 99.99 value for Cu is exclusive of Ag.

④ Hg, max., 1 ppm, (.0001%), Zn, max., 1 ppm, (.0001%); Cd, max., 1 ppm, (.0001%); S, max., 18 ppm, (.0018%); Pb, max., 10 ppm, (.0010%), Se, max., 10 ppm (.0010%); Bi, max., 10 ppm (.0010%), Oxygen max., 10 ppm. (.0010%).

⑤ The 99.99 value includes Cu, Ag and B.

⑥ The total of the seven following elements, Se, Te, Bi, As, Sb, Sn and Mn not to exceed 40 ppm, (.0040%).

⑦ S, max., 15 ppm, (.0015%), Cd, max., 3 ppm, (.0003%), Zn, max., 5 ppm, (.0005%), Hg, max., 1 ppm, (.0001%), Pb, max., 10 ppm, (.0010%), B, (.005-.015%).

⑧ Small amounts of Cd or other elements may be added by agreement to improve resistance to softening at elevated temperature.

⑨ This includes Low Resistance Lake Copper and Electrolytic Copper.

⑩ This includes Oxygen-Free Copper which contains P in an amount agreed upon.

⑪ This includes High Resistance Lake Copper.

⑫ This includes permissible Se

⑬ This includes Oxygen-Free Tellurium Bearing Copper which contains P in an amount agreed upon

⑭ This includes Cu + Ag + Te.

⑮ Other deoxidizers may be used as agreed upon, in which case P need not be present.

⑯ This includes Cu + Ag + S.

⑰ Specific limits are defined as any numerical values, whether maximum only, minimum only, or ranges.

⑱ Co, .20% min.
Ni + Fe + Co, .60% maximum.

⑲ Analysis is regularly made for the elements for which specific limits are listed except Zn. If, however, the presence of other elements is suspected or indicated in the course of routine analysis further analysis shall be made to determine that the total of these "other" elements is not in excess of the limits specified.

⑳ For pipe and tube, the Cu limit may be 83.0% minimum, and the Pb .06% maximum.

㉑ Al + Si, .005% max.

㉒ For tube over 5 inch O.D., the Pb may be less than .20%.

㉓ Copper, 61.0% min. for rod.

㉔ Including Al and Pb.

㉕ Including Mn.

㉖ Including Zn

㉗ Ni + Sn + Mn, 2.0% maximum.

㉘ When both Ni and Si are present, only one shall be i excess of .25%.

NOTES

① The Alloy No. in the Other Designation column is commonly used as the Brass and Bronze Ingot Institute (B.B.I.I.) designation for the equivalent ingot.

② Ni + Co

③ Ni is a residual element and shall not be intentionally added to the melt.

④ For continuous castings, the maximum P shall be 1.5%.

⑤ In determining Cu minimum, Cu may be calculated as Cu + Ni.

⑥ Including Sn and Pb.

⑦ Sn + Pb + Ni + Mn + Fe; Total 1.0% maximum.

⑧ .20% maximum for each element.

⑨ Cu + Sum of Named Elements

⑩ As, Sb and S shall not exceed .05 percent eac and P .01% maximum.

⑪ Total Pb, Zn and Ni shall be 1.0% maximum.

⑫ Cu + Sn + Ni + P shall be 99.5% minimum

⑬ The Fe shall be .35% maximum when used for ste backed bearings.

⑭ For continuous castings, S shall be .25% maximu and Total Other Elements .35% maximum.

⑮ The mechanical properties in the heat treate condition may not be attained if the Pb content e ceeds .01%.

⑯ Fe content shall not exceed Ni content.

⑰ For welding grades, the Pb shall not exceed .01%

⑱ Ingot for Remelting specifications vary from the ranges shown.

Note 1. Grades shown in the above list with prefix letter E are normally made only by the basic electric furnace process. All others are normally manufactured by the basic open hearth or basic oxygen processes but may be manufactured by a basic electric furnace process.

Note 2. The phosphorus and sulphur limitations for each process are as follows:

	Maximum per cent	
	P	S
Basic electric	0.025	0.025
Basic open hearth or basic oxygen	0.035	0.040

Note 3. Small quantities of certain elements, which are not specified or required, are present in alloy steels. These elements are considered as incidental and may be present to the following maximum amounts: Copper, 0.35 per cent; Nickel, 0.25 per cent; Chromium, 0.20 per cent; Molybdenum, 0.06 per cent.

Note 4. Where minimum and maximum sulphur content is shown it is indicative of resulphurized steel.

Note 5. The chemical ranges and limits shown in Table 6-1 are produced to check analysis tolerances shown in Table 6-3.

Note 6. Standard alloy steels can be produced with a lead range of 0.15/0.35 per cent. Such steels are identified by inserting the letter "L" between the second and third numerals of the AISI number, e.g., 41L40. A ladle analysis for lead is not determinable, since lead is added to the ladle stream while each ingot is poured.

HIGH SPEED TOOL STEELS

Symbol M, Molybdenum Types

The high speed steels listed under the letter symbol M are generally considered to have molybdenum as the principal alloying element, although several contain an equal or a slightly greater amount of such elements as tungsten or cobalt. Those types with higher carbon and vanadium contents generally offer improved abrasion resistance, but machinability and grindability may be adversely affected. The series beginning with M41 is characterized by the capability of attaining exceptionally high hardness in heat treatment.

Typical applications.

- Broaches
- Chasers
- Cheeking Tools
- Drills
- End Mills
- Hobs
- Lathe Tools
- Milling Cutters
- Planer Tools
- Punches
- Reamers
- Routers
- Saws
- Taps
- Woodworking Tools

In addition to the above cutting tools, some of these high speed steels are successfully used for such cold work applications as cold header die inserts, thread rolling dies, punches, and blanking dies. For such applications, the high speed steels are frequently hardened from a lower than normal temperature (i.e. underhardened) to increase toughness.

It should be recognized that because of differences in properties, availability, and economic considerations, all of these steels should not be considered for each application.

HOT WORK TOOL STEELS

Symbol H

H1-H19, incl., Chromium Types

These hot work steels are referred to as chromium types, although there may be other significant alloying elements present. The types containing molybdenum, H10, H11, H12 and H13, are the most widely used of all the hot work steels, and are characterized by high hardenability and excellent toughness. They offer the best selection from warehouse stocks.

The chromium-tungsten type H14 and the chromium-tungsten-cobalt type H19 offer greater resistance to softening, but are less ductile in service, and are not as readily available from stock.

Typical hot work applications.

- Bolsters
- Die Casting Dies
- Dummy Blocks
- Extrusion Dies
- Forging Dies
- Gripper Dies
- Hot Header Dies
- Mandrels
- Punches
- Piercing Tools

In addition to the above hot work tooling, some of these hot work steels are used for cold work applications requiring exceptional toughness at high hardness levels. Such uses may include coining dies, forming rolls, and header die casings.

NOTE LEAD When lead is required as an added element to a standard steel, a range of 0.15 to 0.35%, inclusive, is generally used. Such a steel is identified by inserting the letter 'L' between the second and third numerals of the grade number, that is, 10L45

[a] These steels may be produced by the basic open hearth, the basic oxygen, or the basic electric steelmaking process (see SAE J411). Where silicon is required, the following limits and ranges are commonly used: for steel designations up to but excluding SAE 1015, 0.10% max for SAE 1015 to SAE 1025, 0.10% max or ranges of 0.10–0.20%, 0.15–0.30%, 0.20–0.40%, or 0.30–0.60%; for over SAE 1025, ranges of 0.10–0.20%, 0.15–0.30%, 0.20–0.40% 0.30–0.60%

[b] These grades, with max Mn in excess of 1%, have been renumbered 1500 series Table 3. Present 10XX standard designation will be discontinued after 1970.

[c] Certain qualities and commodities are customarily produced to lower limits of phosph and sulfur

[a] Sheet steel surface requirements may be broadly identified as to the end use by the suffix etter "E" for exposed parts requiring a good painted surface and suffix "U" for unexposed arts for which surface finish is unimportant

[b] These steels may be produced by the basic open hearth, the basic oxygen, or the basic lectric steelmaking process (see SAE J411, Carbon and Alloy Steels) Where silicon is required, the following limits and ranges are commonly used: for steel designations up to but excludin SAE 1015, 0 10% max, for SAE 1015 to SAE 1025, 0.10% max or ranges of 0.10–0 20% c 0 15–0 30%, for over SAE 1025 ranges of 0.10–0 20% or 0.15–0 30%

Report of Iron and Steel Division approved June 1911 and last revised by Iron and Steel Technical Committee April 1970.

In 1941, the SAE Iron and Steel Division in collaboration with the American Iron and Steel Institute made a major change in the method of expressing composition ranges for the SAE steels The plan, as nov applied, is based in general on narrower ladle analysis ranges plus certai

[b] When electric furnace steel is ordered, the carbon range is restricted 0.01%, manganese 0.05%, chromium 0.05% up to 1.25% incl and 0.10% over 1.25%. The maximum phosphorus and sulfur is 0.025% each

[c] Boron or lead may be added to these compositions.

[d] Silicon available in ranges of 0.10–0.20%, 0.20–0.35%, and 0.35% maximum (when carbon deoxidized) when so specified by the purchaser.

TABLE II.—*Continued*

[a] For free machining properties the composition of Grade CF-16F may contain suitable combinations of selenium, phosphorus and molybdenum (Grade CF-16F) or of sulfur and molybdenum (Grade CF-16Fa) as follows:

Selenium, phosphorus and molybdenum	
Selenium, per cent	0.20 to 0.35
Phosphorus, max, per cent	0.17
Molybdenum, max, per cent	1.50
Sulfur and molybdenum:	
Sulfur, per cent	0.20 to 0.40
Molybdenum, per cent	0.40 to 0.80

Other combinations of elements for free-machining properties may be agreed upon by the manufacturer and the purchaser.

[b] For the more severe general corrosive conditions, and when so specified, the carbon content shall not exceed 0.10 per cent. This low-carbon grade shall be designated as grade CH-10.

[c] Chemical analysis is not normally required for the elements phosphorus, sulfur and molybdenum, but if they are present in amounts over those stated they may be cause for rejection.

[d] Grade CF-8C shall have a columbium content of not less than 8 times the carbon content and not more than 1.0 per cent. If a columbium-plus-tantalum alloy in the approximate Cb:Ta ratio of 3:1 is used for stabilizing this grade, the total columbium-plus-tantalum content shall not be less than nine times the carbon content and shall not exceed 1.1 per cent.

[e] For grade CB-30 a copper content of 0.90 to 1.20 per cent is optional.

[f] For purposes of determining conformance with these specifications, the observed or calculated value for carbon content shall be rounded off to the nearest 0.01 per cent in accordance with the rounding-off method of the Recommended Practice for Indicating Which Places of Figures Are to Be Considered Significant in Specified Limiting Values (ASTM Designation: E 29).
